

Reservation Successful!

Your hotel reservation has been successfully completed.

Customer: Norielyn Andaya

Room: 104

Room Type: Suite Room

Check-in: 2026-09-22

Check-out: 2026-09-24

Transaction Status
COMMIT

All reservation operations were completed successfully.

[Back to Reservation](#)

Reservation Failed

Reason:

Room 101 is already reserved. Please select another available room.

Transaction Status
ROLLBACK

The reservation was not saved because the transaction failed.

Please select another available room and try again.

How COMMIT and ROLLBACK Protect the Data

The Hotel Reservation System uses **COMMIT** and **ROLLBACK** to make sure that the reservation data is saved correctly. When a customer submits a reservation, the system starts a transaction and performs several database operations, such as checking the room status, adding the reservation, and changing the room status to **Reserved**.

If all operations are successful, the system uses **COMMIT**. COMMIT permanently saves all the changes made during the transaction. This means that the customer's reservation and the updated room status are successfully stored in the database.

If an operation fails, the system uses **ROLLBACK** instead. ROLLBACK cancels the changes made during the transaction. For example, if a customer tries to reserve a room that is already reserved, the transaction fails and the system performs ROLLBACK. This prevents an incomplete or incorrect reservation from being saved.

In this way, **COMMIT saves valid transactions, while ROLLBACK cancels failed transactions**. This helps protect the accuracy and consistency of the hotel reservation data.
